1. Master JSON for Required Tables

Prepare a master JSON containing only the required tables to synchronize metadata from the existing Admin Panel.

Example:

iceberg_data.jan_aadhar_txn.table1
iceberg_data.jan_aadhar_txn.table2
iceberg_data.jan_aadhar_txn.table3
Benefit: Metadata synchronization will be performed only for the required/registered tables, avoiding unnecessary processing.

2. Scheduled Metadata Synchronization

Provide a option to synchronize metadata for all registered tables and by default, synchronization will happen weekly
Store the synchronized metadata in a JSON file for downstream consumption.
This will ensure that the metadata remains up to date without requiring real-time metadata queries.

3. Query Builder – Metadata from JSON

The metadata for below field will be retrieved from the JSON file instead of querying the Presto engine each time but actual data will be retrieved from actual tables
Catalog, Schema, Table, Associated columns

4. Optimize "Add Rule" Section

Current approach: The application fetches distinct values for every column of the selected table.
Impact: Multiple DISTINCT queries are executed against the Presto engine, resulting in unnecessary query execution and resource consumption.
Proposed solution: Fetch distinct column values only for master/reference-data columns, such as: gender, marital_status, country, state etc.
This will significantly reduce the number of queries executed against Presto.

5. Query Monitoring Dashboard

Prepare a dashboard to display all currently running queries initiated by app_user.
The dashboard can provide visibility into:
Running queries, Query start time, Query duration, User, Catalog/schema/table, Query status
This will help in monitoring, troubleshooting, and identifying long-running queries.
